TECHNICAL FIELD

An element for making an electric contact to a contact member for enabling an electric current to flow between said element and said contact member. The element comprising a body having at least a contact surface thereof coated with a contact layer to be applied against said contact member. The contact layer comprises a continuous or discontinuous film comprising a multielement material. The multielement material has equal composition as at least one of a layered carbide and nitride that can be described as $M_{n+1}AX_n$ or M_2BX , where

15 M is a transition metal or a combination of a transition metals, n is 1, 2, 3 or higher, A is an group A element or a combination of a group A element, B is an group B element or a combination of a group B element and X is Carbon, Nitrogen or both.

20 BACKGROUND ART

Recent studies has shown that compounds having the general formula $M_{n+1}AX_n$ exhibit unusual and exceptional mechanical properties as well as advantageous electrical thermal and chemical properties. Despite having high

25 stiffness these compounds are readily machinable, resistant to thermal shock, unusually damage tolerant, have low density and are thermodynamically stable at high temperatures (up to 2300°C in vacuum).

$M_{n+1}AX_n$ compounds have layered and hexagonal structures with $M_{n+1}X_n$

30 layers interleaved with layers of pure A and this is a anisotropic structure which

has exceptionally strong M-X bonds together with weaker M-A bonds, which gives rise to their unusual combination of properties.

$M_{nH}AX_n$ compounds are characterized according to the number of transition metal layers separating the A-group element layers: in 211 compounds there are two such transition metal layers, on 312 compounds there are three and on 413 compounds there are four. 211 compounds are the most predominant, these include Ti_2AlC , Ti_2AlN , Hf_2PbC , Nb_2AlC , $(Nb,Ti)_2AlC$, $Ti_2AlN_{0.5}C_{0.5}$, Ti_2GeC , Zr_2SnC , Ta_2GaC , Hf_2SnC , Ti_2SnC , Nb_2SnC , Zr_2PbC and Ti_2PbC . The only known 312 compounds are Ti_3AlC_2 , Ti_3GeC_2 and Ti_3SiC_2 . Ti_4AlN_3 and Ti_4SiC_3 are the only 413 compounds known to exist at present. A large number of solid solution permutations and combinations are also conceivable as it is possible to form solid solutions on the M-sites, the A-sites and the X-sites of these different phases.

15

The $M_{nH}AX_n$ compounds can be in ternary, quaternary or higher phases. Ternary phases has three elements, i.e. Ti_3SiC_2 , quaternary phases has four elements i.e. $Ti_2AlN_{0.5}C_{0.5}$, and so on. Thermally, elastically, chemically and electrically the ternary phases, quaternary phases or higher phases share many of the attributes of the binary phases.

20

Michel Barsoum has synthesized, characterized and published data on the $M_{nH}AX_n$ phases named above in bulk form ["The $M_{nH}AX_n$ Phases: A New class of Solids", Progressive Solid State Chemistry, Vol. 28 pp201-281, 2000]. His measurements on Ti_3SiC_2 show that it has a significantly higher thermal conductivity and a much lower electrical resistivity than titanium and, like other $M_{nH}AX_n$ phases, it has ability to contain and confine damage to small areas thus preventing/limiting crack propagation through the material. Its layered structure and the fact that bonding between the layers is weaker than along the

25

layers (as in graphite) give rise to a very low friction coefficient, even after six months exposure to atmosphere.

The research groups of Prof. Lars Hultman at Linköping University and Prof. Ulf

- 5 Jansson at Uppsala University have demonstrated that magnetron sputtering process (a sort of Physical Vapor Deposition, PVD) can be used to deposit coatings of Ti_3SiC_2 and other $Mn+1AX_n$ phases onto various substrates at relatively low temperatures (approximately 750-1000 °C) [Palmquist, J.-P., et al., "Magnetron sputtered epitaxial single-phase Ti_3SiC_2 thin films". Applied
- 10 Physics Letters, 2002. 81: p. 835; Seppänen, T., et al. "Structural characterization of epitaxial Ti_3SiC_2 FILM", in Proc. 53rd Annual Meeting of the Scandinavian Society for Electron Microscopy, Tampere, Finland 12-15 June, 2002 (Ed. J. Keränen and K. Sillanpää, University of Tampere, Finland, ISSN 1455-4518, 2002), p. 142-143.]

15

A contact element in an electrical contact arrangement may have many different applications. The contact element is used for making an electric contact to a contact member for enabling an electric current to flow between said element and said contact member. The element comprise a body having

20 at least a contact surface thereof coated with a contact layer to be applied against said contact member. A sliding electric contact arrangement comprising two contact surfaces adapted to be applied to each other for establishing an electric contact may slide with respect to each other when establishing and/or interrupting and/or maintaining the contact action. Such electric contact

25 elements, which may establish sliding contacts or stationary contacts has preferably a body made of for instance copper or aluminum.

The contact layer is arranged for establishing a contact to the contact member with desired properties, such as a low contact resistance and low friction

30 coefficient with respect to the material of the contact member to be contacted etc. Such applications are for instance for making contacts to semiconductor

devices for establishing and interrupting electric contact, in mechanical disconnections and breakers and for establishing and interrupting electric contacts in contact arrangements of plug-in type. Such electric contact elements, which may establish sliding contacts or stationary contacts has
5 preferably a body made of for instance copper or aluminium.

An example of a contact element including a contact layer, such as a continuous film of a multielement material having strong bonds, such as covalent or metallic bonds, within each atomic layer and weaker bonds, through
10 longer bonding distance or for example as van der Waals bonds or hydrogen bonds, between at least some adjacent atomic layers thereof is given in WO01/41167. The multielement material is MoS_2 , WS_2 or of any of layered ternary carbides and nitrides that can be described as M_3AX_2 . A problem with the described multielement material is that methods to produce the material are
15 carried out at high temperatures (700-1400° C). This means that an electrical electric contact element, which has a body made of a material that is not shape resistant at high temperatures, for instance copper or aluminum cannot be made use of.

20 SUMMARY OF THE INVENTION

The object of the present invention is to provide an electric contact element having a contact layer with a low friction without the disadvantages mentioned above of such layers already known in connection with use and/or manufacture
25 thereof.

This object is obtained by providing an element for making an electric contact to a contact member for enabling an electric current to flow between said element and said contact member, said element comprising a body having at
30 least a contact surface thereof coated with a contact layer applied against said contact member, and that said contact layer comprises a film comprising a

multielement material comprising a nanocomposite of M-X, M-A-X and/or M-B-X nanocrystals and amorphous regions with M, A, X elements in one or several phases, such as M-A, A-X, M-A-X, X, M-B, B-X, or M-B-X. The multielement material comprises material with equal or similar composition as at least one of

- 5 a layered carbide and nitride that can be described as $M_{n+1}AX_n$ or M_2BX , where M is a transition metal or a combination of a transition metals, n is 1, 2, 3 or higher, A is an group A element or a combination of a group A element, B is an group B elements or a combination of a group B element and X is Carbon, Nitrogen or both.

10

A nanocomposite is a composite comprising crystals, regions or structures with a characteristic length scale above 0.1 nm and below 1000 nm.

- 15 A preferred $M_{n+1}AX_n$ phase is Ti_3SiC_2 , where the resulting film deposited at low temperature is a nanocomposite of TiC nanocrystals and an amorphous phase with Si-C, Ti-Si-C, Ti-Si and C. This film posses good mechanical, chemical, temperature and contact properties.

- 20 It has been found that low temperature deposition of the multielement laminated structure results in nanocomposite compounds, with single elements, binary phases and ternary phases or a higher order phase depending of the number of atomic elements, with good chemical and contact properties. The composition of the compounds on an average should be equal or similar to the composition of the $M_{n+1}AX_n$ or M_2BX phases, such as A-X, M-A-X and X phases or B-X, M-B-X and X phases. The nanocomposite compounds shows
25 also the desired ductile behaviour, posses non welding properties, shock resistance, chemical inertness, low contact resistance and good high temperatures properties which are all desired properties in electrical contact arrangement. Single phase crystalline microstructure forms large grains
30 structure forms grains from 700° C.

In an embodiment of the invention the multielement material is equal or similar to any of a layered carbide and nitride that can be described as $M_{n+1}AX_n$ or M_2BX . The multielement material is in an amorphous state or nanocrystalline (0.5-500 nm grain size) state. The $M_{n+1}AX_n$ compound has a composition
 5 $M_xA_yX_z$ where $\{0 \leq x, y, z \leq 1; x+y+z=1\}$ or both.

$Ti_xSi_yC_z$ with $x=0.5$ and $0.1 < y < 0.3$ made by magnetron sputtering onto substrates kept at low temperature, $T_s \leq 700^\circ C$, exhibit contact resistance against Ag of 6 $\mu\Omega$ at a force of 800 N, which is comparable with Ag-Ag
 10 contacts. At the same time many useful mechanical properties are comparable in terms of friction, wear, and hardness to the previously known binary metal containing any metal Me and diamond-like carbon compound C, Me-C.

Unlike the diamond-like carbon compound that is designed for high hardness
 15 and thus typically exhibit brittle fracture, the material comprising compounds with equal or similar composition as any of a layered carbide and nitride that can be described as $M_{n+1}AX_n$ or M_2BX and nanocomposites are ductile as seen by wear, scraping, scratching and indenting tests.

20 The A element to M-X compounds improves the afore mentioned properties. The nanocomposite comprising compounds with equal or similar composition as at least one of a layered carbide and nitride that can be described as $M_{n+1}AX_n$ or M_2BX , such as M-X, M-A-X and/or M-B-X nanocrystals and amorphous regions with M, A, X elements in one or several phases, such as M-
 25 A, A-X, M-A-X, X or M, B, X elements in one or several phases, such as M-B, B-X, M-B-X, X. The nanocomposites have metallic or ceramic or mixed character type depending on the composition and processing of the film.

30 The deposited coatings comprising nanocomposites may form a transfer layer of nanolaminated crystalline $M_{n+1}AX_n$ phases or carbon graphite during

mechanical wear of an electrical contact. The phase transformation is driven by the thermo- mechanical energy generated in the contact zone. This layer may exhibit ultralow friction due to easy basal plane slip if the $M_{n+1}AX_n$ phase or graphite phase becomes textured parallel to the coating surface. Thus, the coating would not only be functional, but also self-adapting for the application.

PVD, CVD and other deposition processes involving co-deposition of elemental, precursor or compound sources which can be used to make thin films consisting of multielement material equal or similar to $M_{n+1}AX_n$ compounds, said multielement material comprising a nanocomposite of M-X or M-A-X nanocrystals and amorphous regions with M, A, X elements in one or several phases, such as M-A, A-X, M-A-X, X. Preferably the depositions are made at low substrate temperatures such as in the demonstrated example. Finally, we note the possibility to design a coating with the widest possible range of properties compared to other materials as function of composition x, y, z and to make gradient material in one deposition run by varying the compositions from different sources.

It has turned out that a nanocomposite comprising said multielement material, and/or a metallic layer is excellent as a contact layer on a contact element in question for many reasons. A contact layer comprising such a multielement material, and/or a metallic layer according to the invention used as a contact has low contact resistance. The friction coefficient thereof is very low, typically 0.1-0.4. The metallic layer provides the low contact resistance. Furthermore, in regions where the contact has a high friction said metallic layer can be worn and the said underlying multielement material comprising a nanocomposite of M-X, M-A-X and/or M-B-X nanocrystals and amorphous regions with M, A, X elements in one or several phases, such as M-A, A-X, M-A-X, X, M-B, B-X, or M-B-X.

and said multielement material appears on the surface and reduces the friction. Furthermore, said underlying multielement material provides a low friction and wear resistance. Furthermore, said underlying multielement material also is a mechanical load carrying structure with ductile properties under the thin

5 metallic film. This is due to the fact that the strong bonded M-X layers are arranged alternating with weaker M-A bonds. The bonds between these layers in the multielement material are weak. Accordingly, when multielement material of this type comes into contact with another layer only the uppermost atom layer is sheared against the opposite surface of said contact member resulting
10 in very low friction. The low temperature films are showing equal properties compared to films that possesses a layered crystalline structure. The chemical inertness and the smoothness of the multielement compound also contribute to a low friction. The low friction is also due to grain rotation of the nanocomposite phases, and grain boundary phases or carbon. The multielement material are
15 relatively chemical inert and stable at temperatures exceeding 400 °C. Furthermore, said materials have low tendency to form oxides, which prevent degradation of electric contact to said contact member. Furthermore said multielement material coated or combined with a metallic layer show a ductile performance.

20

Said multielement material with equal or similar composition as a $M_{n+1}AX_n$ or M_2BX compound, will have a morphology varying from amorphous or nanocrystalline to pure crystalline, and the morphology may be selected in accordance with the particular use of the contact element and the costs for
25 producing the multielement material.

According to a preferred embodiment of the invention the multielement material of said film coated or combined with a metallic layer is in the range 0.001 μm to 1000 μm , and in a very preferred embodiments is less then 5 μm . Said film of
30 metallic layer is in the range of a fraction of an atomic layer to 1 mm. Such coatings may have a lifetime being nearly indefinite thanks to the very low

friction and wear resistance of this material, so that in closed systems the result aimed at will be achieved through a thin film having low costs of material and manufacturing process as a consequence thereof.

- 5 According to another preferred embodiment of the invention the multielement material coated or combined with a metallic layer is above 5 μm . Such a thickness is preferred in the case of using such a film on a contact element in a contact arrangement where the contact element and the contact member are going to be moved with respect to each other, such as in a sliding contact, and
- 10 accordingly not only moved by different coefficients of thermal expansion upon thermal cycling, such as when used on a slip ring in an electric rotating machine.

- According to another preferred embodiment of the invention the nanocomposite
- 15 multielement film is a blend of different $M_{n+1}AX_n$ and/or $M_2 BX$ compounds where the resulting phases and atomic ratio of the elements are depended on the atomic elements in the $M_{n+1}AX_n$ and/or $M_2 BX$ phases and the ratio between the materials.

- 20 According to another preferred embodiment of the invention the body deeper under said contact surface is made of material being non-resistant to corrosion, and the material last mentioned is coated by a corrosion resistant material such as nickel, adapted to receive said film on top thereof. It is preferred to proceed in this way, since the multielement material film may have pores with a risk of
- 25 corrosion of the underlying body material therethrough.

- Another object of the present invention is to provide sliding electric contact arrangement of the type defined in the introduction allowing a movement of two contact surfaces applied against each other while reducing the inconveniences
- 30 discussed above to a large extent.

This object is according to the invention obtained by providing such an arrangement with a contact element according to the present invention with said film arranged to form a dry contact with a very low friction coefficient, below 0.2, preferably below 0.1, to a contact member.

5

The basic features and advantages of such a contact arrangement are associated with the characteristics of the contact element according to the present invention and appear from the discussion above of such a contact element. However, it is pointed out that a "sliding electric contact" includes all
10 types of arrangements making an electric contact between two members, which may move with respect to each other when the contact is established and/or interrupted and /or when the contact action is maintained. Accordingly, it includes not only contacts sliding along each other by action of an actuating member, but also so called stationary contacts having two contact elements
15 pressed against each other and moving with respect to each other in the contacting state as a consequence of magnetostriction, thermal cycling and materials of the contact elements with different coefficients of thermal expansion or temperature differences between different parts of the contact elements varying over the time.

20

A contact arrangement of the type last mentioned constitutes a preferred embodiment of the present invention, and the contact elements may for instance be pressed with a high pressure, preferably exceeding 1 MPa against each other without any mechanical securing means, but the contact elements
25 may also be forced against each other by threaded screws or bolts.

According to another preferred embodiment of the invention said contact arrangement is adapted to be arranged in an electric rotating machine, where the film comprising multielement material will result in a number of advantages.

30

It is in particular possible to benefit from the low friction coefficient of the multielement material when arranging the contact element and the contact

member of the contact arrangement on parts of the rotating machine moving with respect to each other, such as for instance the slip ring as a contact element and a contact element sliding thereupon. It will in this way be possible to replace the carbon brushes used in the electric rotating machines by a contact element according to the present invention and a film of said type is then also preferably arranged on the moving part, such as a slip ring. Said carbon brushes have a number of disadvantages, such as a restricted lifetime, since the carbon is consumed. Furthermore, carbon dust is spread out on the windings and other parts of the machine, which may disturb the function thereof. It is preferred to have a thickness of the film of multielement material exceeding 10 μm for such a contact element, since also the film of multielement material will be consumed, but comparatively slowly, in this application thereof.

Electrical contacts arrangements according to other preferred embodiments of the invention are different kinds of contacts having contact surfaces moving while bearing against each other in establishing and/or interrupting an electric contact, such as plug-in contacts or different types of spring-loaded contacts, in which it is possible to take advantage of the very low friction coefficient of a multielement material resulting in a self-lubricating dry contact without the problems of lubricants such as oils or fats while making it possible to reduce the operation forces and save power consumed in actuating members.

Electrical contacts arrangements according to other preferred embodiments of the invention are included in tap changers on transformers, where a low friction is a great advantage when the contact elements are sliding with their contact surfaces against each other, and in mechanical disconnectors and breakers and in relays.

The invention also relates to a use of the contact arrangement according to any of the claims according to the invention relating to a contact arrangement, in

which a probe for measuring and testing an integrated circuit is covered with said multielement material film, a contact layer is coated/combined with a metallic layer, avoiding chemical degradation and metal cladding on the probe. It is self evident that this use according to the invention is very favourable, since it will make it possible to carry out measurements and testing without any interruptions for replacing or cleaning the probe.

The invention also relates to a use of the contact arrangement according to any of claims according to the invention relating to a contact arrangement in which a contact for enabling contact to an electronic device, such as an integrated circuit (IC) is covered with a said multielement material film enabling electrical contact to the device.

Further advantages as well as advantageous features appear from the following description and the other dependent claims.

BRIEF DESCRIPTION OF THE DRAWINGS

With reference to the appended drawings, below follows a specific description of preferred embodiments of the invention. In the drawings;

Figure 1A depicts a structure of a multielement material layer comprising nanocomposites with nanocrystals mixed with amorphous regions,

Figure 1B depicts another structure of a multielement material layer comprising nanocomposites with nanocrystals mixed with amorphous regions,

Figure 2 depicts a structure of a multielement material layer with regions in a nanocrystalline state,

Figure 3 depicts a structure of a multielement material comprising a metallic layer,

5 Figure 4 depicts a structure of a multielement material layer laminated with metallic layers in a repeated structure,

Figure 5 illustrates an electric contact element of plug-in type according to a preferred embodiment of the invention,

10 Figure 6 is a sectioned view of an electric contact element of helical contact type according to another preferred embodiment of the invention,

15 Figure 7 is a partially sectioned and exploded view of an arrangement for making an electric contact to a power semiconductor device according to a preferred embodiment of the invention and

Figure 8 illustrates schematically a contact arrangement of a contact arrangement according to a preferred embodiment of the invention in electrical equipment.

20

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Figure 1A depicts a structure of a multielement material layer with equal or similar composition as any of a layered carbide and nitride that can be described as $M_{m+1}AX_n$ or M_2BX , where M is a transition metal or a combination of a transition metals, n is 1, 2, 3 or higher, A is an group A element or a combination of a group A element, B is an group B element or a combination of a group B element and X is Carbon, Nitrogen or both, comprising a nanocomposite of M-X, M-A-X and/or M-B-X nanocrystals and amorphous regions with M, A, X elements in one or several phases, such as M-A, A-X, M-A-X, X and/or M, B, X elements in one or several phases, such as M-

25

30

B, B-X, M-B-X, X. The multielement material has amorphous regions (denoted G in the figure) mixed with regions in of the multielement material in a nanocrystalline state (denoted C, D, E in the figure). The individual regions (denoted C, D and E in the picture) in the structure is a single element, binary phases, ternary phases and/or higher order phases depending on the number of atomic elements in the film.

Figure 1B depicts a structure of a multielement material with the elements that is described in the description to figure 1A. The multielement material has amorphous regions with M-A, A-X, M-A-X and X phases or BX, M-B-X and X phases (denoted G in the figure) mixed with regions in of the multielement material in a nanocrystalline state, M-A-X and/or M-X or M-B-X and/or M-X of $M_{n+1}AX_n$ or $M_2 BX$ phases of which some is surrounded by an amorphous layer (denoted J, K, L in the figure), or crystalline layer (denoted C, D, E in the figure), of a pure M-A, A-X, M-A-X and X phases or BX, M-B-X and X phases material (denoted C, D, E in the figure).

Figure 2 depicts a structure of a multielement material with the elements that is described in the description to figure 1 layer with regions in a nanocrystalline state, (denoted C, D, E in the figure). The individual regions (denoted C, D and E in the picture) in the structure is a single element, binary phases, ternary phases and/or higher order phases.

Figure 3 depicts a structure of a multielement material U with the elements that is described in the description to figure 1 comprising a metallic layer Me.

Figure 4 depicts a structure of multielement material layers with the elements that is described in the description to figure 1 layer laminated with metallic layers Me in a repeated structure. The multielement material layers in amorphous regions mixed with regions in a nanocrystalline state (denoted U in the figure).

Figure 5 illustrates an electric contact element of plug-in type according to a preferred embodiment of the invention,

5 Figure 5 shows a contact arrangement 1 of plug-in type, in which a contact surface 2 on a contact element 3 slides along and while bearing against contact surfaces 4 on another contact element 5, here called contact member. The contact element 3 has a female character and is present in the form of a resilient jaw adapted to be connected to the male contact member 5 in the form
 10 of a contact rail. The contact element 3 is applied on the contact member 5 and bears in the contacting state while being biased by means of at least a contact surface 2 against a contact surface 4 on the contact member 5. At least one of the contact surfaces 2 and 4, preferably both, are provided with a continuous or discontinuous multielement material film according to the invention said film a
 15 comprising a multielement material with equal composition as any of a layered carbide and nitride that can be described as $M_{n+1}AX_n$ or M_2BX , where M is a transition metal or a combination of a transition metals, n is 1, 2, 3 or higher, A is an group A element or a combination of a group A element, B is an group B element or a combination of a group B element and X is Carbon, Nitrogen or
 20 both and the multielement material comprising a nanocomposite of M-X, M-A-X and/or M-B-X nanocrystals and amorphous regions with M, A, X elements in one or several phases, such as M-A, A-X, M-A-X, X, M-B, B-X, or M-B-X.

The class of material is also denoted as $(n+1)1(n)$ compounds. The
 25 multielement material could also have a composition corresponding to a H-phase material that can be described as M_2BX , where M is a transition metal; B is a group B element and X is either C or N. This film has a thickness in the range of 0.001 μm to 1000 μm , and it will have a very low friction coefficient, typically 0.01 to 0.1. This means that the friction forces to be overcome when
 30 controlling the contact arrangement for establishing or interrupting the electric contact will be very low, resulting in a low necessary power consumption in an

actuating member and a nearly neglectible wear of the of the contact surfaces constituted by this film. Furthermore, the film is chemical inert and stable at temperatures exceeding 400° C. It is pointed out that it is well possible that said continuous or discontinuous film is arranged on only the contact member 5,

5 which of course is a contact element just as the contact element 3.

Furthermore, in this case the film comprising multielement material is deposited and adheres to the body 6 of the contact element 3, but in other preferred embodiments of the invention it is well possible that said film coats a body being laid on top thereof as a separate foil. This may in particular be the case

10 for the embodiment shown in Fig. 3 described further below. The continuous or discontinuous film comprising the multielement material may be deposited on the body of the contact element, being preferably of Cu, by different kinds of Physical Vapour Deposition (PVD), Chemical Vapour Deposition (CVD), electrochemically, electroless deposition or with thermal plasma spraying. It is preferred to provide a thin layer of a corrosion resistant material on the body
15 before applying said film would the body be of a material being non-resistant to corrosion, since it is possible that the film will have some pores reaching therethrough.

20 Fig 6 illustrates a further example of a contact arrangement in which it is advantageous to coat at least one of the contact surfaces with a continuous or discontinuous film comprising a multielement material, according to the invention said film forming a self lubricating dry contact with a very low friction according to the present invention. This embodiment relates to a helical contact
25 arrangement having a contact element 7 in the form of a spring-loaded annular body such as a ring of a helically wound wire adapted to establish and maintain an electric contact to a first contact member 8, such as an inner sleeve or a pin, and a second contact member 9, such as an outer sleeve or a tube. The contact element 7 is in contact state compressed so that at least a contact
30 surface 10 thereof will bear spring-loaded against a contact surface 11 of the first contact member 8, and at least another contact surface 12 of the first contact

element 7 will bear spring-loaded against at least a contact surface 13 of the second contact member 9. According to this preferred embodiment of the invention at least one of a contact surfaces 10-13 is entirely or partially coated with a continuous or discontinuous low friction film comprise the multielement material. Such a helical contact arrangement is used for example in an electrical breaker in a switchgear device.

An arrangement for making a good electric contact to a semiconductor component 14 is illustrated in Fig 7, but the different members arranged in a stack and pressed together with a high pressure, preferably exceeding 1 MPa and typically 6-8 MPa, are shown spaced apart for clarity. Each half of the stack comprises a pool piece 15 in the form of a Cu plate for making a connection to the semiconductor component. Each pool piece is provided with a thin continuous or discontinuous film 16 comprising multielement material, and a metallic layer. The coefficient of thermal expansion of the semiconductor material, for instance Si, SiC or diamond, of the semiconductor component and of Cu differs a lot ($2,2 \cdot 10^{-6} / \text{K}$ for Si and $16 \cdot 10^{-6} / \text{K}$ for Cu), which means that the Cu plates 15 and the semiconductor component 14 will move laterally with respect to each other when the temperature thereof changes. Contact arrangements of this type according to the stand of the art require for that sake one or several further members in said stack between the pool piece and the semiconductor component for taking care of this tendency to mutual movements upon thermal cycling for avoiding cracks in the semiconductor component and/or wear of the contact surface of said component. However the very low friction of a film according to the present invention makes it possible to omit all these additional members and making the contact arrangement less costly, not at the least by allowing the issue of a cheap material without any need of thermal matching close to there semiconductor component. A contact arrangement of this type is a part of power electronic encapsulation 17 forming a closed system, and practically no material will be consumed when the film moves along the semiconductor component upon thermal cycling so that the

lifetime thereof will be practically indefinite. The multielement contact layer 16 can also be deposited directly on the semiconducting device 14 or both on the Cu pole piece 15 and the device 14.

5 Figure 8 illustrates schematically an electric contact arrangement of plug-in type, for example used in electrical equipment. The members are arranged to be pressed together but are shown spaced apart for clarity. The contact arrangement has a first contact member 41, which has male character, and second contact member 42, which has female character. The first contact
10 member 41 is adapted to be connected to the second contact member 42, by means of at least a contact surface 43 on the first contact member against a contact surface 44 on the second contact member. At least one of the contact surfaces 43 and 44, preferably both, are provided with a continuous or discontinuous film comprising the multielement material.

15

A contact element and a sliding electric contact arrangement according to the present invention may find many other preferred applications, and such applications would be apparent to a man with ordinary skill in the art without departing from the basic idea of the invention as defined in the appended
20 claims.

25

It would for example be possible to dope the thin friction film for improving friction, thermal, mechanical or electrical properties by one or several compounds. However, the amount of doping should not exceed 20 % of the weight of the film. It is then also possible to have different films on different contact surfaces of the contact elements and the contact member, for instance some doped and others not or some formed by at least two sub-layers and others having only one layer.

30

Another example of a contact arrangement according to the invention is to cover a probe for measuring and testing an integrated circuit (IC) with said film,

comprising a multielement material and a metal layer, avoiding chemical degradation and metal cladding on the probe.

5 Furthermore, the contact elements and arrangements of the invention are not restricted to any particular system voltages, but may be used on low, intermediate and high voltage applications.

10 The multielement material of the contact layer according to the invention may form an solid film together with 50-90% of metal, for instance of Ti or Au, for improving the conductivity. This may take place by forming a homogeneous dispersion of the metal in the material, inhomogeneous dispersion with metallic regions and multielement regions, such as a composite or by arranging a layer of the multielement chemical compound and a layer of the metal alternatingly.

CLAIMS

1. An element for making an electric contact to a contact member (5, 15, 19, 41) for enabling an electric current to flow between said element and said
5 contact member, said element (3, 14, 42) comprising a body (6) having at least a contact surface (2, 4, 16, 43, 44) thereof coated with a contact layer applied against said contact member, and that said contact layer comprises a film comprising a multielement material with equal composition as at least one of a layered carbide or nitride that is described as $M_{nH}AX_n$ or $M_2 BX$ compounds,
10 where M is a transition metal or a combination of a transition metals, n is 1, 2, 3 or higher, A is an group A element or a combination of a group A element, B is an group B element or a combination of a group B element and X is Carbon, Nitrogen or both, **characterised in** that said multielement material comprise at least one nanocomposite comprising single elements, binary
15 phases, ternary phases or higher order phases based on the atomic elements in the corresponding $M_{nH}AX_n$ or $M_2 BX$ compound.

2. An element according to claim 1, **characterised in** that said nanocomposite comprise at least two of the following phases: M-A, A-X, M-A-X,
20 X, M-X, M-B-X, M-B, B-X, or M-B-X or a combination of said materials.

3. An element according to any of claim 1 or 2, **characterised in** that said nanocomposite comprise at least one of the following of M-X, M-A-X and M-B-X nanocrystals (C, D, E) and at least one of the following amorphous
25 regions (J, K, L) with M, A, X elements in one or several phases, such as M-A, A-X, M-A-X, X and M-B, B-X or M-B-X.

4. An element according to any of the preceding claims,
characterised in that said transition metal is Titan; Ti, n is 1, 2, 3 or
30 higher, X is C; Carbon and A is at least one of Silicon; Si, Germanium; Ge or Tin; Sn or a combination of said atomic elements.

5. An element according to any of claims 1-3, **characterised in** that that said multielement material is Ti_3SiC_2 and the nanocomposite comprise at least one of the following Si-C, Ti-Si-C, Ti-Si, C or a combination of said materials.
6. An element according to any of claims 1, 2, 4 or 5, **characterised in** that said nanocomposite of the multielement material of said film is at least partially in an amorphous state.
7. An element according to any of claims 1, 2, 4 or 5, **characterised in** that said nanocomposite of the multielement material of said film is at least partially in a nanocrystalline state.
8. An element according to any of preceding claims, **characterised in** that said nanocomposite of the multielement material of said film has amorphous regions mixed with regions in a nanocrystalline state.
9. An element according to any of the preceding claims, **characterised in** that said film comprise individual regions (C, D, E) that is single element, binary phases, ternary phases and/or higher order phases of said layered carbide and nitride.
10. An element according to any of the preceding claims, **characterised in** that said film comprise a nanocomposite which composition correspond to a combination of different $M_{nH}AX_n$ and/or M_2BX phases.
11. An element according to any of the preceding claims, **characterised in** that the thickness of said film is in the range of a fraction of an atomic layer to 1000 μm

12. An element according to any of the preceding claims,
characterised in that the thickness of said film is in the range of
0.0001 μm to 1000 μm .
- 5 13. An element according to any of the preceding claims,
characterised in that the thickness of said film is in the range of a
fraction of an atomic layer to 5 μm .
- 10 14. An element according to any of the preceding claims,
characterised in that said film comprise a metallic layer (Me), the
thickness of the metallic layer is in the range of a fraction of an atomic layer to
1000 μm .
- 15 15. An element according to any of the preceding claims,
characterised in that said multielement material layer is laminated
with metallic layers (Me) in a multilayer structure.
- 20 16. An element according to any of the preceding claims,
characterised in that said multielement material has a coat of said
metallic layer (Me), in that the contact surface is metallic (Me).
- 25 17. An element according to any of the preceding claims,
characterised in that said multielement material comprise individual
regions (C, D, E) that is a single element, binary phases, ternary phases and/or
higher order phases with an average composition equal to or similar to said
layered carbide and and nitride.
- 30 18. An element according to any of the preceding claims,
characterised in that the metallic layer covers grains or regions of the

multielement material, with the total film thickness is in the range 0.0001 μm to 1000 μm .

19. A element according to any of the preceding claims,
5 **characterised in** that said film is continuous.

20. A element according to any claims 11-16, **characterised in**
that said film is discontinuous.

10 21. A element according to any of the preceding claims,
characterised in that said film is deposited on said body and adheres
thereto.

22. A contact element according to any of the claims 1-21,
15 **characterised in** that said film is arranged as freestanding foil to be
applied against said contact member when making said electric contact.

23. A contact element according to any of the preceding claims,
characterised in that said film is doped by one or several compounds
20 for altering and improving friction, mechanical, thermal and electrical properties
of said film.

24. A contact element according to claim 21 or 23, **characterised**
in that said film is formed on said body by means of an chemical method such
25 as a electroless or a electrolytic process.

25. A contact element according to claim 21 or 23, **characterised**
in that said film is deposited on said body by the use of a vapour deposition
technique.

26. A contact element according to claim 25, **characterised in** that said film is deposited on said body by Physical Vapour Deposition (PVD) or Chemical Vapour Deposition (CVD).
- 5 27. A contact element according to claim 21 or 23, **characterised in** that said film is deposited on said body by dipping the body in a chemical solution or spraying it on said body through for example thermal or plasma spraying.
- 10 28. A contact element according to claim 21, **characterised in** that said film is deposited using a combination of the techniques according to claims 23-27.
- 15 29. A sliding electric contact arrangement, i.e. a contact arrangement in which two contact surfaces (2, 4) adapted to be applied against each other for establishing an electric contact may slide with respect to each other when establishing and/or interrupting and/or maintaining the contact action, **characterised in** that it has a contact element (3, 42) according to any of the preceding claims with said film arranged to form a dry contact with a
 20 very low friction coefficient, below 0.6, preferably below 0.1, to a contact member (5, 41).
30. An arrangement according to claim 29, **characterised in** that said contact member (5, 41) has also a contact surface (4) coated with a film
 25 comprising a multielement material film.
31. An arrangement according to claim 29 or 30, **characterised in** that the surfaces of the contact element (15) and the contact member (14) adapted to applied against each other for establishing said electric contact are
 30 allowed to move with respect to each other as a consequence of magnetostriction or different coefficients of thermal expansion of the materials

of surface portions of the contact element and the contact member upon temperature changes of the contact element and the contact member.

32. A contact arrangement according to claim 31, **characterised in**
5 that the contact element (15) and the contact member (14) are adapted to be pressed towards each other for establishing said contact.

33. An arrangement according to claim 32, **characterised in** that
10 the contact element (15) and the contact member (14) are adapted to be forced against each other by bolts or screws for establishing said electric contact there between.

34. An arrangement according to any of claims 29-33, **characterised**
15 **in** that one (5, 41) of the contact element and the contact member is male-like and the other (3, 42) is female-like, and that the contact element and the contact member are adapted to establish said electric contact by being brought into engagement with each other.

35. An arrangement according to any of claims 29-33, **characterised**
20 **in** that it comprises means for spring-loading the contact element and the contact member against each other for making said electric contact

36. An arrangement according to any of claims 29-33, **characterised**
25 **in** that one of the contact element and the contact member belong to two parts of a mechanical disconnecter movable away from each other for disconnecting two terminals thereof.

37. An arrangement according to any of claims 29-33, **characterised**
30 **in** that one of the contact element and the contact member belong to two parts of a mechanical breaker movable away from each other for breaking the current path between the terminals thereof.

38. An arrangement according to any of claims 29-33, **characterised in** that one of the contact element and the contact member belong to a crimp contact.

5

39. Use of a contact arrangement according to any of claims 29-38, in which a contact for enabling contact to an electronic device, such as an integrated circuit (IC) is covered with a said multielement material film enabling electrical contact to the device.

10

40. Use of a contact arrangement according to any of claims 29-38, in which a probe for measuring and testing an integrated circuit (IC) is covered with a said multielement material film avoiding chemical degradation and metal cladding on the probe.

5 ABSTRACT

An element for making an electric contact to a contact member 5, 15, 19, 41 for enabling an electric current to flow between said element and said contact member, said element 3, 14, 42 comprising a body 6 having at least a contact surface 2, 4, 16, 43, 44 thereof coated with a contact layer applied against said contact member. The contact layer comprises a film comprising a multielement material with equal or similar composition as any of a layered carbide or nitride that can be described as $M_{n+1}AX_n$ or M_2BX , where M is a transition metal or a combination of a transition metals, n is 1, 2, 3 or higher, A is an group A element or a combination of a group A element, B is an group B element or a combination of a group B element and X is Carbon, Nitrogen or both.
